Assignment 4 - Diastolic Blood Pressure (DBP)

Diastolic Blood Pressure or DBP is basically the pressure in your arteries when your heart is resting between beats. A normal DBP should sit between 60 and 80 mmHg. If it drops below 60 that means the heart isn't pushing enough pressure through the body which could mean the patient is dehydrated, losing blood or going into shock. If it goes above 90 that means the pressure is too high which over time can lead to serious things like strokes or heart attacks. In the ED a triage nurse checks DBP alongside systolic pressure straight away because together they tell you how well the heart is actually coping. Anything outside that 60 to 80 range needs to be flagged quickly
